SUMMARY

This report provides an aerodynamic analysis and outlines methods used in obtaining the aerodynamic "Rf" for the solution of the optimum transport propelloplane under contract Nonr 1657 (00). The combination of aerodynamics and weights "Rf" (Reference 2) by the method described in Reference 1 yielded the optimum aircraft.

Minimum gross weight was considered to be the criterion for optimum selection. A three view drawing of the optimum aircraft is provided on the following page.

2.0 GENERAL CONSIDERATIONS AND ASSUMPTIONS

2.1 Engine Characteristics

Generalized shaft turbine engine characteristics according to Reference 3 for the year 1965 were used. Specific fuel consumption versus % NRP curves are repeated in Figure 2 for easy reference.

The contribution of turbine jet thrust to forward flight propulsion was not considered, since its effect was small at the flight speeds encountered and insignificant on a comparative basis as affecting the optimum selection.

2.2 Gear Box "Derating"

As a result of the gear boxes being derated, the power output per two engine combination is limited to 75 percent of sea level NRP.

2.3 Drag

The equivalent parasite drag area, f , was computed to be 41.2 ft² in cruise configuration with external fuel tanks. This value was assumed constant for the matrix of possible aircraft considered.

2.4 Power Required

Airplane thrust horsepower required is defined by the following expression:

$$THP_r = \frac{\frac{\rho}{\rho_0} V^3 f}{96100} + \frac{W_G \left(\frac{W_G}{S} \right)}{3.47 AReV \frac{\rho}{\rho_0}}$$

$$\text{Let } K = \frac{W_G \left(\frac{W_G}{S} \right)}{3.47 ARe} \quad (1)$$

$f = 41.2$ (see 2.3), then

$$THP_r = \frac{\frac{\rho}{\rho_0} V^3}{2330} + \frac{K}{\frac{\rho}{\rho_0} V} \quad (2)$$

2.5 Power Available

In order to describe the available thrust horsepower characteristics of an aircraft, the following must be known.

1. Installed Horsepower
2. Propeller Diameter.
3. BAF
4. Tip Speed
5. Altitude
6. Type of Propeller, i.e. Single or Dual Rotation
7. Propeller Characteristics, i.e. Variation of Propeller Efficiency with Forward Speed.

Items 1-3 were obtained on the basis of the 6000' 95°F hover ceiling requirement and minimum power package weight. A complete discussion of this is contained in Reference 2.

Items 4-5 Variables.

Item 6 Dual rotating propellers were used.

Item 7 Propeller characteristics were obtained from Reference 5.

For purposes of illustration, Figures 7 through 10 show the variation of propeller efficiency and thrust horsepower with forward flight velocity at various percentages of shaft horsepower for the optimum aircraft (Figure 1).

2.6 Engine Operation

The transport propelloplane under consideration provides for a total of 8 engines and 4 nacelles (2 engines per nacelle). When cruising at less than full power, a number of possible operating combinations exist. It is the object of this section to determine a schedule of engine operation which will require the least fuel and still be consistent with safe operating procedures. The assumption is made that the applied thrust must at all times be symmetrical; therefore, engines must be shut down in pairs and propellers must be feathered in pairs.

2.6.1 Engine Operation Within a Single Nacelle

Let the 2 engines be denoted A and B, then

$$\frac{\text{FUEL}}{\text{HR}} = \text{SFC}_{\text{NET}} \text{ SHP}_P = \text{SFC}_A \text{ SHP}_A + \text{SFC}_B \text{ SHP}_B$$

$$\frac{\text{FUEL}}{\text{SHP}_P - \text{HR}} = \text{SFC}_{\text{NET}} = \text{SFC}_A \frac{\text{SHP}_A}{\text{SHP}_P} + \text{SFC}_B \frac{\text{SHP}_B}{\text{SHP}_P}$$

$$\text{SHP}_A + \text{SHP}_B = \text{SHP}_P$$

$$\text{let } R_A = \frac{\text{SHP}_A}{\text{SHP}_P} \quad R_B = \frac{\text{SHP}_B}{\text{SHP}_P} \quad \text{then, } R_A + R_B = 1.0$$

$$\text{Also, } \frac{1}{2}(\% \text{ NRP}_A) + \frac{1}{2}(\% \text{ NRP}_B) = \% \text{ NRP}_P \quad (3)$$

$$\text{SPC}_{\text{NET}} = \text{SFC}_A R_A + \text{SFC}_B R_B \quad (4)$$

$$\frac{R_A}{R_B} = \frac{\text{SHP}_A}{\text{SHP}_B} = \frac{\% \text{ NRP}_A}{\% \text{ NRP}_B} \quad (5)$$

Using the specific fuel consumption characteristics of Figure 2, the SFC_{NET} is plotted against $\% \text{ NRP}_P$ for various R_A/R_B in Figure 11. It is seen that the operating procedure for minimum fuel occurs when both engines are operated at the same $\% \text{ NRP}$. Below 50% NRP_P the procedure for minimum fuel consumption is to shut down one engine completely, thereby operating the remaining engine at a high $\% \text{ NRP}$ and consequently lower specific fuel consumption.

2.6.2 % NRP - 75-100%

For the total required power falling in the range of 75 to 100% of available power, there are two possible operating procedures:

1. Maintain all 8 engines at the same % NRP.
2. Maintain one pair of nacelles, say, the outboard at 100%NRP while varying the inboard as required.

To evaluate these two possibilities, the following equations are developed.

Let subscript, i, denote inboard,
subscript, o, denote outboard,
subscript, 8, denote 8 engine or total.

$$\frac{\text{TOTAL FUEL}}{\text{HR}} = \text{SFC}_i \text{ SHP}_i + \text{SFC}_o \text{ SHP}_o$$

but $\text{SHP} = \frac{\text{THP}}{\eta}$; therefore

$$\frac{\text{TOTAL FUEL}}{\text{HR}} = \text{SFC} \frac{\text{THP}_i}{\eta_i} + \text{SFC} \frac{\text{THP}_o}{\eta_o} \quad (6)$$

$$\text{Let } R_i = \frac{\frac{\text{THP}_i}{\eta_i}}{\frac{\text{THP}_8}{\eta_8}}, \quad R_o = \frac{\frac{\text{THP}_o}{\eta_o}}{\frac{\text{THP}_8}{\eta_8}} \quad \text{Then,}$$

$$\frac{R_i}{R_o} = \frac{\frac{\text{THP}_i}{\eta_i}}{\frac{\text{THP}_o}{\eta_o}} \quad (7)$$

$$\text{THP}_i + \text{THP}_o = \text{THP}_8 \quad (8)$$

Combining (7) and (8)

$$\text{THP}_o = \frac{\text{THP}_8 \frac{\eta_o}{\eta_i}}{\frac{R_i}{R_o} + \frac{\eta_o}{\eta_i}}, \quad \text{THP}_i = \frac{\text{THP}_8 \frac{R_i}{R_o}}{\frac{R_i}{R_o} + \frac{\eta_o}{\eta_i}}$$

CONFIDENTIAL

PREPARED	NAME	DATE	HILLER HELICOPTERS	PAGE

APPROVED			Contract Nonr 1657 (00)	REPORT NO

CONFIDENTIAL

2.6.2 % NRP 75-100% (Continued)

and substituting these in (6)

$$\frac{\text{FUEL}}{\text{THP} \cdot \text{HR}} = \frac{\text{SFC}_i}{\eta_i} \left(\frac{\frac{R_i}{R_o}}{\left(\frac{R_i}{R_o} + \frac{\eta_o}{\eta_i} \right)} \right) + \frac{\text{SFC}_o}{\eta_o} \left(\frac{\frac{\eta_o}{\eta_i}}{\left(\frac{R_i}{R_o} + \frac{\eta_o}{\eta_i} \right)} \right) \quad (9)$$

From Equation (7) and (8)

$$\frac{\eta_i}{\eta_8} R_i + \frac{\eta_o}{\eta_8} R_o = 1 \quad (10)$$

From Equation (7)

$$\frac{R_i}{R_o} = \frac{\% \text{NRP}_{ei}}{\% \text{NRP}_{eo}} \quad (11)$$

Also,

$$\frac{1}{2} \frac{\eta_i}{\eta_8} \% \text{NRP}_{ei} + \frac{1}{2} \frac{\eta_o}{\eta_8} \% \text{NRP}_{eo} = \% \text{NRP}_8 \quad (12)$$

Using the above relations the two possible operating procedures evaluated on two representative aircraft (Figure 12). It is seen that the minimum fuel is required when both inboard and outboard nacelles are maintained at the same power (Alternate 1).

2.6.3 % NRP - 40 to 75%

In this range the following engine operating alternatives exist:

1. 8 engines operating at same % NRP.
2. 6 engine operation as follows: (Assume 2 outboard engines shut down.)
 - a. All 6 engines at same % NRP, that is, $R_i/R_o = 2$
 - b. Maintain single outboard engines at 100% and vary inboard as required.

Equations for 6 engine operation are obtained in similar manner to 2.6.2.

$$\frac{1}{2} \frac{\eta_i}{\eta_o} \% \text{NRP}_{ei} + \frac{1}{4} \frac{\eta_o}{\eta_o} \% \text{NRP}_{eo} = \% \text{NRP}_8 \quad (13)$$

$$\frac{R_i}{R_o} = 2 \frac{\% \text{NRP}_{ei}}{\% \text{NRP}_{eo}} \quad (14)$$

Evaluation of the above operating procedures is provided by the same two representative aircraft (Figure 12). Minimum fuel requirements are obtained in this range by operating six engines at the same power (Alternative 2a).

2.6.4 % NRP 50% or Less

From the preceding sections it has been found desirable to shut down engines whenever possible and to operate the remaining ones at the same percent of power. In view of this, then, the possibility of operating 6 or 8 engines in this range may be eliminated. The two remaining alternatives are:

1. One pair of propellers feathered, 4 engines in 2 nacelles operating.
2. 4 engines in 4 nacelles operating.

CONFIDENTIAL

PREPARED	NAME	DATE	HILLER HELICOPTERS	PAGE	20
CHECKED			TITLE	MODEL	1048
APPROVED			Aerodynamic Analysis Report For Transport Propelloplane Study Contract Nonr 1657 (00)	REPORT NO	114.7

CONFIDENTIAL

2.6.4 % NRP 50% or Less (Continued)

The apparent advantage of operating half of the propellers at higher power and, hence, higher efficiency must be weighed against the increased drag of the feathered propellers.

From Reference 6 for a three bladed propeller,

$$D = \frac{\rho v^2 D_p^2 T_C}{3}$$

and for a six bladed propeller,

$$\Delta THP_r = \frac{2Dv}{550}, \text{ or}$$

$$\Delta THP_r = \frac{2 \rho v^3 D_p^2 T_C}{3(550)}$$

For evaluating THP_r the following conditions are assumed:

1. Turbine torque is zero (assumes the use of shutters or vanes); therefore $Q_C = 0$, $\beta_{.75R} = 85$, and $T_C = .008$.
2. Comparison is made at sea level standard conditions.
3. Comparison is made at minimum mission speed of 260 knots.

The expression for ΔTHP_r is, then, $\Delta THP_r = 1.96 D_p^2$

The increase in available THP for the same SHP that would result from supplying the required power by one propeller at higher efficiency rather than two at reduced efficiency is listed in the table below for representative aircraft.

Corresponding THP_r due to the feathered propeller is also tabulated for comparison.

CONFIDENTIAL

CONFIDENTIAL

2.6.4 % NRP 50% or Less (Continued)

WH	WG	VT	Dp	Δ THP _a	Δ THP _r
40	40000	800	20.36	1300	810
	80000	to 1000	28.80	2200	1620
100	40000		12.86	300	320
	80000		18.20	400	645

From the above table there appears to be little advantage in feathering propellers. Furthermore, the selection of the optimum is facilitated and not affected by considering all propellers in operation.

2.6.5 Fuel Consumption

This section provides the method used to calculate fuel consumption with engines operating according to the schedules for minimum fuel of the preceding sections.

$$\frac{\text{TOTAL FUEL}}{\text{HR}} = \text{SFC}_i \frac{\text{THP}_i}{\eta_i} + \text{SFC}_o \frac{\text{THP}_o}{\eta_o} \quad (15)$$

2.6.5.1 8 Engine Operation

For a given flight condition the total required THP is evenly divided between inboard and outboard nacelles, thus,

$$\text{TOTAL THP}_r = \text{THP}_i + \text{THP}_o$$

$$\eta_i = \eta_o, \text{ and}$$

$$\text{SFC}_i = \text{SFC}_o ; \text{ therefore}$$

$$\frac{\text{TOTAL FUEL}}{\text{HR}} = \text{SFC} \frac{\text{THP}_r}{\eta}$$

CONFIDENTIAL

PREPARED	NAME	DATE	HILLER HELICOPTERS	MODEL
CHECKED			TITLE: Air Required Analysis Report For Transport Propellor Study	REPORT NO.
APPROVED			Contract No. 1057 (10)	

CONFIDENTIAL

2.6.5.1 8 Engine Operation (Continued)

The calculation procedure is, then

- Read THP_r at the given flight condition (Figure 3 or 4).
- Read percent of normal rated power of propeller shaft, % NRPp (Figure 7 or 9).
- Read η at % NRPp (Figure 8 or 10).
- % NRP_e = % NRPp for 8 engine operation. Read SFC at NRP_e (Figure 2.).

2.6.5.2 6 Engine Operation

The total required THP is not evenly divided between inboard and outboard nacelles; however it is convenient to determine a relationship for total fuel/hr which is independent of individual nacelle operation, hence,

$$\frac{\text{TOTAL FUEL}}{\text{HR}} = \text{SFC} \frac{THP_r}{\eta_8} \quad \text{where}$$

THP_r = Total required thrust horsepower

η_8 = propeller efficiency for 8 engine operation and is read at the percent of 8 engine normal rated power. This relation is based on the assumption that

$$\frac{THP_r}{\eta_8} = \frac{THP_i}{\eta_i} + \frac{THP_o}{\eta_o}$$

Although the propellers are operating at different efficiencies, the compensating variation of THP_i and THP_o is sufficient to make the assumption reasonably valid for the matrix.

SFC = effective specific fuel consumption and is read at

$$\frac{\% NRP_8}{.75}$$

with reference to equation (13) with all 6 engines at the same % NRP.

CONFIDENTIAL

PREPARED	NAME	DATE	HILLER HELICOPTERS	PAGE
CHECKED			TITLE	MODEL
APPROVED			Transport Propeller Data Study	REPORT NO
			Contract Four 1017 (00)	11.0

CONFIDENTIAL

2.6.5.2 6 Engine Operation (Continued)

$$\% \text{ NRP}_e = \frac{\% \text{ NRP}_g}{\frac{1}{2} \frac{\eta_i}{\eta_g} + \frac{1}{4} \frac{\eta_o}{\eta_g}}$$

The denominator,

$$\frac{1}{2} \frac{\eta_i}{\eta_g} + \frac{1}{4} \frac{\eta_o}{\eta_g},$$

when checked over the matrix is found to remain nearly constant at .75.

Fuel/hr is calculated as follows:

- Read THP_r at the given flight condition (Figure 3 or 4).
- Read percent of 6 engine normal rated power, $\% \text{ NRP}$ (Figure 7 or 9).
- Read η_g at $\% \text{ NRP}_g$ (Figure 8 or 10).
- Read SFC at $\frac{\% \text{ NRP}_g}{.75}$ (Figure 2.).

2.6.5.3 4 Engine Operation

The total required THP is evenly divided between inboard and outboard nacelles, thus,

$$\text{TOTAL THP}_r = \text{THP}_i + \text{THP}_o$$

$$\eta_i = \eta_o \quad \text{and}$$

$$\text{SFC}_i = \text{SFC}_o ; \text{ therefore}$$

$$\frac{\text{TOTAL FUEL}}{\text{HR}} = \text{SFC} \frac{\text{THP}_r}{\eta}$$

2.6.0 Engine Operation (Continued)

25,000' Operation

% 8 ENGINE NRP	ENGINE OPERATION	% NRP/ENGINE	% NRP AT WHICH TO READ SFC
100 - 75	8 engines at same % NRP	100 - 75	Same as 8 engine % NRP
75 - 50	6 engines at same % NRP	75 - 50	$\frac{8 \text{ Engine \% NRP}}{.75}$
50 or less	4 engines at same % NRP All propellers operating	50 or less	$\frac{8 \text{ Engine \% NRP}}{.5}$

2.7 Rate of Climb

Rate of climb is obtained from the expressions:

$$\frac{R}{C} = \frac{33000}{W_G} (THP_a - THP_r) \quad (16)$$

Figure (13) is a graphical solution of equation (16) for rapid calculation of rate of climb. The maximum rate of climb is obtained at the velocity where the difference between THP_a and THP_r is greatest.

2.8 Rate of Descent

Equation (17) defines airplane rate of descent with power on.

$$\frac{R}{D} = \frac{33000}{W_G} (THP_r - THP_a) \quad (17)$$

2.9 Installed Horsepower

The sea level installed horsepower can be readily determined if the ratio

$$\frac{\text{Sea Level Propeller Thrust}}{\text{Hover ceiling altitude propeller thrust} + \text{engine jet thrust}}$$

$$= \frac{\text{Sea Level Propeller Thrust}}{\text{Gross Weight}}$$

is known. This ratio is dependent upon propeller and engine characteristics. For the dual rotating propellers, gas turbine power plants, 6000', 95°F hover ceiling, and matrix under consideration, this ratio was found to remain essentially constant at 1.3.

3.0 SPECIFIED AIRCRAFT PERFORMANCE AND MISSION REQUIREMENTS

The specified aircraft performance and mission requirements are listed below.

- 3.1 Required payload is 7000 lbs. outbound and 4000 lbs. return.
- 3.2 Hover ceiling 6000', 95°F.
- 3.3 Cruise speed 300 MPH minimum (260 knots).
- 3.4 Mission per Figure 14.

3.5 Total Mission Fuel

To determine the total fuel required for the mission, and hence, the "RFR", the mission is broken down into component parts. Fuel required for each part is determined, the summation of these providing the total mission fuel.

3.5.1 Starting Fuel

A starting and maneuvering time of 2 minutes per flight leg is assumed, giving a total of 4 minutes. During this time 8 engines are assumed to be operating at 75% NRP. It is further assumed that the operation is at sea level.

$$F_S = SFC (t)(SHP)$$

$$SFC = .43$$

$$t = \frac{4}{60}$$

$$SHP = 75\% \text{ of total installed power}$$

$$F_S = .0287 \text{ SHP}$$

3.5.2 Reserve Fuel

Reserve fuel is assumed to be 10% of total fuel.

3.5.3 Climb Fuel

The following assumptions are made regarding climb fuel.

- A climb to 25000 feet in the shortest time is assumed most economical.
- Rate of climb at sea level is calculated with 8 engines operating at 75% NRP due to gear box derating.
- Rate of climb at 25000' is calculated with 8 engines operating at 100% NRP (100% NRP at 25000 feet is equal to 60% sea level NRP, Reference 3).
- A linear variation of SHP, SFC, VC, and R/C between sea level and 25000 ft. is assumed.

CONFIDENTIAL

PREPARED BY	NAME	HILLER HELICOPTERS	PAGE
CHECKED	DATE		MODEL
APPROVED			REPORT NO

CONFIDENTIAL

3.5.3 Climb Fuel Consumption

Fuel consumed during climb is calculated as follows:

$$F_C = R_C \frac{SFC}{V_C} SHP \quad \text{where}$$

$$R_C = \frac{V_C \Delta H}{60 \frac{R}{C}} \quad \text{and}$$

V_C = average climb velocity between S.L. and 25000 feet for maximum rate of climb.

R_C = Range credit during climb.

ΔH = 25000 feet.

$\frac{R}{C}$ = Average rate of climb between S.L. and 25000' (Reference to Section 2.7)

SHP = Average SHP between S.L. and 25000'.

SFC = Average SFC between S.L. and 25000'.

3.5.4 Descent Fuel

Calculation of descent fuel is based on the following assumptions.

- Rate of descent, R/D , is constant at 2500 ft/min.
- Descent velocity, V_D , = 300 knots.
- Most economical engine operation per section 2.6 is assumed.
- A linear variation of SHP, and SFC between 25000' and S.L. is assumed.

$$F_D = R_D \frac{SFC}{V_D} SHP \quad \text{where}$$

$$R_D = V_D \frac{\Delta H}{60 \frac{R}{D}}$$

V_D = 300 knots

ΔH = 25000'

$\frac{R}{D}$ = 2500 ft/min.

3.5.3 Climb Fuel (Continued)

Fuel required during climb is calculated as follows:

$$F_C = R_C \frac{SFC}{V_C} SHP \quad \text{where}$$

$$R_C = \frac{V_C \Delta H}{60 \frac{R}{C}} \quad \text{and}$$

V_C = average climb velocity between S.L. and 25000 feet for maximum rate of climb.

R_C = Range credit during climb.

ΔH = 25000 feet.

$\frac{R}{C}$ = Average rate of climb between S.L. and 25000' (Reference to Section 2.7)

SHP = Average SHP between S.L. and 25000'.

SFC = Average SFC between S.L. and 25000'.

3.5.4 Descent Fuel

Calculation of descent fuel is based on the following assumptions.

- Rate of descent, R/D , is constant at 2500 ft/min.
- Descent velocity, V_D , = 300 knots.
- Most economical engine operation per section 2.6 is assumed.
- A linear variation of SHP, and SFC between 25000' and S.L. is assumed.

$$F_D = R_D \frac{SFC}{V_D} SHP \quad \text{where}$$

$$R_D = V_D \frac{\Delta H}{60 \frac{R}{D}}$$

V_D = 300 knots

ΔH = 25000'

$\frac{R}{D}$ = 2500 ft/min.

3.5.4 Descent Fuel (Continued)

$$R_D = \text{N.Mi}$$

SFC = Average between 25000' and S.L.

SHP = Average between 25000' and S.L. May be obtained from equation (17).

3.5.5 Cruising Fuel - 25,000'

$$\text{Fuel for 25000' cruise} = \frac{R}{V} \left(\frac{\text{Fuel}}{\text{HR}} \right) \text{ where}$$

$\left(\frac{\text{Fuel}}{\text{HR}} \right)$ is obtained according to Section 2.6.5.

V is cruise velocity. It is selected for minimum fuel/mile, but according to mission requirements, in no case less than 260 knots.

$$R = 245 \text{ N.Mi}$$

3.5.6 Cruising Fuel - Sea Level

$$\text{Fuel for sea level cruise} = \frac{R}{V} \left(\frac{\text{Fuel}}{\text{HR}} \right) \text{ where}$$

$\left(\frac{\text{Fuel}}{\text{HR}} \right)$ is obtained according to Section 2.6.5

V is cruise velocity for minimum fuel/mile, and equal to or greater than 260 knots.

$$R = 74 \text{ N.Mi}$$

3.5.7 Return Half of Mission

The return half of mission is identical to the outbound half except for the gross weight which is reduced by the amount of the fuel used for the first half and 4000 lbs. payload. The predominant effect of the lower gross weight is in the reduction of induced drag of which the term "K" (Section 2.4) is a function.

For the purpose of determining outbound fuel requirements for the matrix range of wing loadings and aspect ratio a plot is made of fuel versus "K". Figure (15) is such a curve presented for purposes of illustration. From this curve the half mission fuel can be read for my combination of W/S and AR. Also, from this same curve the return fuel can be read at the new value of "K" for the return half.

5.1 Power Required

Figure 17 is a plot of shaft horsepower required and available for sea level standard conditions. Power required for the transition region was calculated according to the method provided by Reference (7).

5.2 Jet Thrust

Figure 18 shows the effect of turbine jet thrust on cruising fuel economy. As originally assumed, the difference in fuel consumption is negligible.

5.3 Best Cruise Speed

Figure 18 also shows the velocity for minimum fuel consumption to be 260 knots at sea level and 300 knots at 25,000'.

5.4 Take-Off Distance

Distances required for running take-off to clear a 50 ft. obstacle are provided by Figure 19. The methods of References 8 and 4 were employed and assume a level, smooth concrete runway, sea level standard conditions.

Figure 19.

5.5 Off-Design Operation

Figure 20 shows the range-payload capabilities of this aircraft when fuel and payload are interchanged. Also, as shown, the capabilities are further enhanced when an overloaded running take-off is permitted from home base with a vertical landing and take-off at the remote base.

6.0 MODEL 1048-B

Contract Nonr 1657 (00) was extended an additional period of time in order to establish an aircraft capable of meeting the specified mission and hover ceiling using engines, propellers, and other components available for production in the year 1960.

Two more requirements of the mission were added, namely:

1. Fuel required shall be computed as 2.2 times the fuel required for the first half of the mission. This method of computation is essentially the same as the method used for the main study except that the small reduction in fuel required for the second half due to reduced gross weight is not accounted for.

a.0 MODEL 1048-B (Continued)

2. The specific fuel consumption shall be increased 5% over the manufacturer's guaranteed value.

Mission and hover ceiling requirements are met by the use of water-alcohol injection for the initial take-off. The aircraft reaches design gross weight of 93000 lbs. for the first landing at the remote base.

The following tabulation lists the physical characteristics and performance.

Take-Off Gross Weight	= 101,000 lbs.
Design Gross Weight	= 93,000 lbs.
Fuel Weight	= 18,500 lbs.
Disk Loading	= 64.05 lb/ft ²
Wing Loading	= 90 lb/ft ²
Propeller Diameter	= 21.5 ft.
No. Blades	= 6 (Dual)
Activity Factor	= 135/Blade
Tip Speed	= 900 FPS
Aspect Ratio	= 6.5
Wing Area	= 1032 ft ²
Span	= 81.9 ft.

Installed Horsepower: 8 Allison 550-B1 Engines @ 4590 NRP

Water-Alcohol	= 1450 lbs.
Stall Speed, Sea Level, Standard-Power Off	= 125 knots
Cruise Speed, Sea Level	= 270 knots
Cruise Speed, 25000 feet	= 300 knots
Maximum Speed, Sea Level (75% NRP)	= 365 knots
Maximum Speed, 25000 feet	= 465 knots
Rate of Climb, Sea Level, 75% NRP	= 6860 FPM
Rate of Climb, 25000 feet, 100% NRP	= 5800 FPM

Hover @ 6000 ft., 95°F, Take-Off Gross Weight requires 76% maximum available power + water/alcohol injection.

Hover Ceiling, Standard Atmosphere, Maximum

Power + Water/Alcohol Injection	= 18,650 ft.
Service Ceiling, NRP, Wg	= 49,200 ft.
Static Thrust, S.L., 75% NRP	= 106,300 lbs.
Static Thrust, S.L., 100% NRP	= 127,000 lbs.

Vertical R/C, 6000 ft., 95°F, Maximum Power,
 + Water/Alcohol Injection, WT.O. = 3,950 FPM
 Vertical R/C, S.L., 75% NRP, Take-Off WG = 1,520 FPM
 Ferry Range @ 20% Overload, 25000 ft Cruise
 Altitude, 10% Reserve = 2,050 N.Mi.

7.0 MODEL 1048-D

A brief investigation was made as to the type of mission that could be made with Model 1048-A using presently available engines and propellers.

As specified, 20 percent of the mission is flown at sea level. With a 6000 lb. payload a mission radius of 270 N.Mi. can be flown. Hot Day (95°F) hover ceiling of 6000 feet is met with the use of water/alcohol injection for the initial take-off and for the first landing at the remote base.

On the other hand, the specified mission radius of 369 N.Mi. with 8000 lbs. payload can be met if the hover ceiling is reduced to 6200 feet standard altitude.

The following tabulation lists the characteristics of Model 1048-D.

Take-Off Gross Weight = 83,600 lbs.
 Payload = 6,000 lbs.
 Fuel = 13,000 lbs.
 Water/Alcohol = 2,900 lbs.
 Propeller Diameter = 19.08 ft.
 No. Blades = 8 (Dual)
 Activity Factor = 135/Blade
 Tip Speed = 900 FPS
 Engines - 8 Allison 501-D8 @ 3316/Engine, S.L., NRP .
 Weight @ First Landing = 71250 lbs.
 Hover Ceiling, NRP, Standard, Take-Off
 Gross Weight (No Water/Alcohol Injection) = 6200 ft.
